MEMORANDUM REPORT NO. NAL 710/720

Final Report on Problem 3-7.6

30 January 1945

Resistance of M1 Helmets of Varying Thicknesses and
of M1 Helmets Fitted with Plastic Liners to Perforation by the
Soft and Hard Types of Caliber .45 M1 Garand Ball Ammunition

ABSTRACT

Ballistic tests conducted upon the fronts and backs of M1 helmets of varying thicknesses showed marked increases in ballistic resistance up to thicknesses of 0.035" to 0.037" above which thickness the increase was negligible. The front of the M1 helmet has a ballistic limit approximately 5% higher than the back. The plastic liner was found to behave in a brittle manner and to have no effect upon the ballistic resistance of M1 helmets. The replacement of the liner by an equivalent weight of steel in the helmet shell resulted in a considerable increase in the ballistic efficiency.

I Authority

O.O. 421/3260, Wtn 421/454, dated 1st August 1944
O.O. 421/3395, Wtn 421/486, dated 22 November 1944
The above letters are contained in Appendix A.

II Introduction

A. Discussion

It had been determined in the Detroit Ordnance District that it was possible to reduce the depth of draw of the M1 helmet by as much as $1\frac{1}{4}$ " without impairing the fit of the plastic liner into the helmet. It was suggested that the reduction in the depth of draw would result in the production of lighter weight helmets which would be thicker, nevertheless,

UNCLASSIFIED

than the normal M1 helmets in the zone below the top of the crown where the reduction in gage is at a maximum. In addition, it was believed that the resultant decrease in the extent of cold working would prove effective in lowering the residual stresses and thus help alleviate the age cracking problem.

Mr. E. F. Baldwin of the Detroit Ordnance District Office has developed a removable fabric suspension which can be attached by clips to a metal headband spot welded to the inside of the M1 helmet shell. This development was made with the idea of replacing the plastic liner, which weighs approximately 9 $\frac{1}{2}$ to 10 ounces, with an equivalent weight of steel in the helmet shell for the purpose of improving the ballistic resistance. It was found that the helmet shell could be increased in thickness by approximately 0.008" (25%) and, when fitted with Mr. Baldwin's suspension, weigh no more than the present M1 helmet fitted with a plastic liner.

B. Object of Tests

1. To determine the ballistic limits of 0.043" and 0.046" thick Hadfield steel discs.
2. To determine what increase in ballistic efficiency is obtained by fabricating helmets from thicker steel stock.
3. To determine whether or not the slight changes in curvature and design resulting from the decreased depth of draw result in changes in the ballistic resistance.
4. To determine the ballistic characteristics of the plastic liner when assembled into the M1 helmet as a unit.
5. To compare the ballistic resistance of M1 helmets fitted with plastic liners to steel helmets of equivalent weight.

III Conclusions

1. When tested with the gilding metal jacketed, soft lead cored caliber .45 M1911 pistol ball ammunition, the ballistic limits of both the front and the back of the helmets increased rapidly with increasing thickness of the helmets up to 0.037", above which thickness the increase was slight.
2. When tested with the copper clad steel jacketed, hard lead cored caliber .45 M1911 pistol ball ammunition, the ballistic limits of both the front and the back of the helmets increased rapidly with increasing thickness up to 0.035", above which thickness no apparent increase occurred.

3. The front of the helmet possesses greater ballistic resistance than the back, averaging approximately 50 ft./sec. higher against the soft projectiles and 35 ft./sec. against the hard projectiles.

4. The plastic liner for the M1 helmet behaves in a brittle manner under ballistic impact, fragments being broken off and the liner cracking even when the helmet shell itself is not penetrated by the projectile.

5. The plastic liner is completely ineffective in increasing the ballistic resistance of the M1 helmet, whereas replacing the liner by an equivalent weight of metal in the helmet shell resulted in a substantial increase in the ballistic efficiency.

6. Since no regular draw and reduced draw helmets of the same gage were submitted for proof testing, no exact conclusion regarding the effect of reduced draw upon the ballistic characteristics of the M1 helmet is possible. The ballistic tests which were conducted, however, indicate that little, if any, change in ballistic resistance results from the slight changes in curvature and design accompanying the reduced depth of draw.

7. The copper clad steel jacketed, hard lead cored caliber .45 M1911 pistol ball ammunition yielded ballistic limits from 130 to 170 ft./sec. lower than the gilding metal jacketed, soft lead projectiles when fired at helmet discs of the gages tested, and from 120 to 290 ft./sec. lower when fired at helmets.

8. The ballistic performance of materials tested with projectiles which deform upon impact is greatly influenced by the deforming characteristics of the testing projectiles. Lower ballistic limits result from the use of projectiles which are more resistant to deformation.

IV Description of Material

The material received for test consisted of the following items:

20 . . . helmet discs, 0.043" thick.

20 . . . helmet discs, 0.046" thick.

20 . . . helmets, Steel M1, regular draw, 0.032" thick at back (station No. 8).

20 . . . helmets, Steel M1, regular draw, 0.035" thick at back (station No. 8).

20 . . . helmets, Steel M1, reduced draw, 0.034" thick at back (station No. 8).

20 . . . helmets, Steel M1, reduced draw, 0.037" thick at back (station No. 8).

- 20 . . . Helmets, Steel M1, reduced draw, 0.038" thick at back (station No. 8).
- 10 . . . Helmets, Steel M1, regular draw, 0.040" thick at back (station No. 8).
- 10 . . . Helmets, Steel M1, regular draw, 0.032" thick at back (station No. 8) and 0.032" to 0.035" thick at front (station No. 4).
- 10 . . . Plastic helmet liners.

The weights and serial numbers of the helmets and liners are contained in Appendix B.

The projectiles used consisted of two types of caliber .45 M1911 pistol ball ammunition. One lot consisted of gilding metal jacketed soft lead cores, Lot E.C. 24704X, produced by the Evansville Ordnance Plant. This lot was found to conform in chemical analysis, hardness, and ballistic characteristics to projectiles described as types "No. 1 and 3" in Watertown Arsenal Memorandum Report No. WAL 710/351*. These soft projectiles are currently being used for the acceptance testing of helmets at the producers' plants. The second lot of projectiles consisted of copper clad steel jacketed hard lead cores similar to type "No. 5" described in the above report.

The gun used was a caliber .45 Thompson sub-machine gun barrel fitted with a Springfield M1903 bolt action.

V Details of Test

A. Procedure

Ballistic limits were obtained on eight randomly selected discs of each gage (.043" and .046") using the soft projectiles against four of the discs and the hard projectiles against the remaining four. The discs were rigidly clamped to a wooden framework which provided a 14" x 7" unbacked area for ballistic testing.

The twenty helmets of each gage (.038", .034", .035", .037", and .038") were divided into two equal groups, each comprising ten helmets of each gage. One group was tested with the soft projectiles and the other with the hard projectiles. The ballistic limits of each unit of ten helmets of the same gage were obtained at both the front (station No. 4) and the back (station No. 8). The locations of the stations are

*Watertown Arsenal Memorandum Report No. WAL 710/351 - "Comparison of the Physical, Chemical, and Ballistic Properties of Various Lots of Caliber .45 M1911 Pistol Ball Ammunition Used for the Proof Testing of Helmets and Body Armor Components". 4 December 1944.

illustrated in Figure 1. The stations are located along a longitudinal plane passed through the middle of the helmet, with the number 4 position lying $5\frac{1}{2}$ " up from the rim of the visor as measured on the surface of the helmet, and the number 8 position lying $5\frac{1}{4}$ " up from the back of the helmet. These two positions coincide with the regions of maximum reduction in gage occurring during the deep drawing of the helmet shell. The ballistic acceptance test of the "M1 helmet is always conducted at the front (station No. 4) of the helmet.

The helmets were mounted on a wooden frame for ballistic testing in such manner that the projectiles impacted the helmets normal to the tangent of the impacted surfaces, see Figure 1. The gun was mounted on a tripod at a distance of 25 feet from the target. The striking velocities were measured by means of an Aberdeen chronograph connected to screens placed 10 feet apart; the nearest one being 10 feet from the gun.

Ballistic limits were obtained at both the number 4 and 8 stations by firing at successive helmets of the same gage with varying velocities until partial and complete penetrations were obtained at velocities within 50 ft./sec. of each other. In the majority of cases at least 2 partial penetrations and 2 complete penetrations were obtained at velocities with \pm 25 ft./sec. of the ballistic limit velocity.

B. Results and Discussion

A summary of the results of the ballistic tests is contained in Table 1. The results of the tests of the helmets of various gages are plotted graphically in Figures 2 and 3, and the detailed ballistic records are contained in Appendix C.

The ballistic results obtained from firing at flat helmet discs with both the soft and hard projectiles are comparable to those previously obtained upon similar material in the past^{*} and are indicative of satisfactory quality material.

The fronts (station No. 4) of the helmets were found to be consistently superior to the backs (station No. 8) in ballistic resistance, averaging approximately 50 ft./sec. higher against the soft projectiles and 35 ft./sec. against the hard projectiles. Unfortunately, except for one group of helmets, only the backs (station No. 8) were gaged. Examination of a relatively large amount of production data on hand at this arsenal indicate that the station No. 4 position generally averages

* Watertown Arsenal Memorandum Report No. WAL 710/351 op. cit. also, Watertown Arsenal Memorandum Report No. WAL 710/635 "Ballistic Tests of 0.040" - 0.050" Haafield Steel Sheet with Caliber .45 Ball Projectiles for Development of Specification Requirements." 18 May 1944.

0.001" greater in thickness than the station No. 8 position. The difference in the ballistic properties of the front and the back of the M1 helmet cannot be entirely attributed to the difference in thickness of these two zones and may in part be traceable to differences in curvature, hardness, and residual stress conditions.

Figure 4 contains photographs of the front and the back of a helmet after ballistic testing, showing the partial penetration of the front at a velocity of 842 ft./sec., whereas the back was completely penetrated at a velocity of 614 ft./sec. The extensive indenting of the helmet upon partial penetration is characteristic of the effect produced by the easily deforming gilding metal jacketed soft lead bullets. Upon complete penetration, the soft bullets generally produce large holes which result from the tearing out and folding back of large flaps of metal. The copper clad steel jacketed hard lead bullets, on the other hand, deform to a much lesser degree than the soft bullets and produce characteristically different penetrations and lower ballistic limit values, see Figure 5. Since the hard bullet deforms less, the striking energy is distributed over a smaller area while less of the bullet's kinetic energy is used in self-deformation, allowing the bullet to penetrate at lower velocities than the soft bullets. For the same reasons, the hard bullets generally produce smaller openings upon complete penetration than result from the penetration of soft bullets. Since the hard bullets produce lower ballistic limits, partial penetration by the hard bullets occur at lower striking velocities, resulting in less indentation and deformation at the region of impact.

Figure 6 contains photographs of two helmets, one .035" thick and the other 0.040" thick at the back (station No. 8). Both were impacted with gilding metal jacketed soft lead bullets. The upper photograph again indicates the superior ballistic resistance of the front of the helmet, while the lower photograph shows partial penetration of both the front and the back at relatively high velocities, demonstrating the increased ballistic resistance of thicker helmets.

The plastic helmet liner was found to behave in a brittle manner under ballistic attack and to contribute nothing to the ballistic efficiency of the M1 helmet. The upper photograph of Figure 7 shows a helmet which had been partially penetrated by a gilding metal jacketed soft lead bullet. The lower photograph of Figure 7 shows the plastic helmet liner which was fitted into the helmet during the ballistic testing. The liner was extensively cracked and a piece was knocked out, even though the helmet shell had not been penetrated by the bullet.

Figure 8 shows the inside of a liner which had been fitted into a helmet during the ballistic testing. Complete penetration of the helmet by soft projectiles resulted in the cracking and breaking of the plastic liner in the vicinity of the impacts.

The comparison between the ballistic properties of 0.032" thick M1 helmets fitted with plastic liners and steel helmets of equivalent weight is shown in Table I. The M1 helmets fitted with plastic liners were considerably thicker in the front than in the back, averaging 0.035"

at station No. 4. By comparing the ballistic properties of the M1 helmets fitted with plastic liners to those of the backs of .032" thick helmets and the fronts of 0.034" and 0.035" thick helmets it is apparent that the liner produces no change whatsoever in the ballistic resistance of the M1 helmet. Steel helmets of equivalent weight to M1 helmets fitted with liners averaged 0.040" thick at the back (station No. 8). These helmets were found to have considerably higher ballistic limits than the thinner helmets fitted with liners.

Since the plastic liner contributes nothing to the ballistic efficiency of the M1 helmet, the use of a weight of approximately 10 ounces in the form of a non-protective covering may well be questioned. It is believed that consideration should be given to the design of a helmet which has a thickness at station number 4 and 8 of not less than 0.037", and with a sturdy suspension attached to the inside of the helmet shell to seat the helmet firmly upon the head and at the same time keep the inside surface of the helmet from coming into contact with any portion of the head.

Analysis of production data covering a total of 510 helmets reveals that 46.8% of the total production has a thickness at the front (station No. 4) of 0.032" or less. Figures 2 and 3 point to the unnecessarily low ballistic efficiency of almost half the currently produced helmets. The results of this ballistic program definitely indicate the advisability of increasing the thickness of the M1 helmet.

If changes in the design and thickness of helmets are contemplated, it would probably be necessary to conduct fragmentation tests to determine the resistance of various types of helmets to penetration by odd shaped fragments of greatly varying size and velocity. Such tests could be performed by placing a group of helmets around a 20mm H.E. shell so that all helmets present identical surfaces to the fragments resulting from the detonation of the shell. Such tests must of necessity be conducted upon a statistical basis using a sufficient number of helmets and tests to yield significant results. The weight and number of fragments penetrating and being retained inside the helmets could be used to evaluate their ballistic efficiency. Similar tests of flat helmet steel and body armor components have been conducted at the Ordnance Research Center, Aberdeen.

The helmets having the normal depth of draw were 0.032" and 0.035" thick at station No. 8, whereas the reduced draw helmets were 0.034", 0.037", and 0.038" thick at station No. 8. Consequently, no exact determination could be made of the effect upon the ballistic properties of the changes in curvature and design resulting from the reduced draw. The results of the ballistic tests indicate, however, that little if any changes in ballistic behavior resulted from the changes in curvature induced by the reduced draw.

The weights of the helmets submitted for ballistic testing are contained in Appendix B, and a graph showing the relationship between the

weight and the thickness of helmets is shown in Figure 9. The effect of the reduced draw upon the weight of helmets could not be determined since the regular draw helmets were not in the finished condition, whereas the reduced draw helmets were fitted with edging, loops, and chin straps, and were painted. Figure 9 indicates that an increase of gage of 0.001" is accompanied by an increase in weight of approximately one ounce.

APPENDIX A
Correspondence

WAR DEPARTMENT
OFFICE OF THE CHIEF OF ORDNANCE
WASHINGTON, D. C.

73819

Attn:
SPOIS

14 August 1944

Subject: Helmet, Steel M1

To: Commanding Officer
Watertown Arsenal
Watertown, Mass.

1. Attached herewith in duplicate is shipping order, SAD 4021, covering the shipment of the following helmets to your arsenal for ballistic test:

a. 50 - Helmets, Steel M1 fabricated from steel stock of $.044 \pm .003$ with same depth of draw as current helmets.

b. 50 - Helmets, Steel M1 fabricated from steel stock of $.044 \pm .003$ with $\frac{1}{4}$ " reduced depth of draw.

c. 50 - Helmets, Steel M1 fabricated from steel stock of $.046 \pm .003$ with same depth of draw of current helmets.

d. 50 - Helmets, Steel M1 fabricated from steel stock of $.046 \pm .003$ with $\frac{1}{4}$ " reduced depth of draw.

2. Each helmet is to be tagged to indicate the method of fabrication together with the depth of draw and thickness and location of the thinnest section. It is requested that your office determine the ballistic limits on these helmets in an attempt to determine which of the four groups produced the highest ballistic limits. In addition, it is requested that all helmets be fired at a minimum of one shot on the top of the crown in an attempt to determine the maximum depth of indentation without penetration. The purpose of this test is to determine:

a. Whether or not the helmets fabricated with $\frac{1}{4}$ " reduced depth of draw will give higher ballistic limits.

b. To determine what increase in ballistic efficiency is obtained by fabricating helmets from thicker steel stock.

It is understood that these helmets will be shipped to your arsenal within the next few days from the McCord Radiator & Mfg. Co. After the ballistic determinations have been made, it is requested that your office submit the results by indorsement hereon prior to the memorandum report.

By order of the Chief of Ordnance:

(S/I) F. X. VOLBERG
Major, Ord. Dept.
Assistant

22 November 1944

Subject: Helmet, Steel M1

To: Commanding Officer
Watertown Arsenal
Watertown, Mass.

Attn: Major N. A. Matthews

1. Attached herewith are duplicate copies of shipping order, SAD 4241, covering shipment of 10 helmets, Steel M1 (.040 thickness weighing 48 ounces plus or minus two ounces) and 10 Helmets, Steel M1 (.032 thickness at thinnest spot with helmet liner, plastic). It is requested that ballistic limits be made on the 10 helmets weighing 48 ounces plus or minus two ounces and also that ballistic limits be determined on the 10 helmets of .032 thickness with the helmet liner plastic in place. It is requested that the point of impact be at station number 4 and station number 8 located by measuring $\frac{1}{2}$ " between stations from the front of the visor on a line in the longitudinal plane of the helmet.

2. On shipping order, SAD 4243, duplicate copies attached, the following material is being forwarded:

20 . . . Helmet Discs (.043 thickness)
20 . . . Helmet Discs (.046 thickness)
20 . . . Helmet Discs (.050 thickness)
20 . . . Helmets, Steel M1 (regular draw thickness .032)
20 . . . Helmets, Steel M1 (regular draw thickness .035)
20 . . . Helmets, Steel M1 (reduced draw thickness .034)
20 . . . Helmets, Steel M1 (reduced draw thickness .037)
20 . . . Helmets, Steel M1 (reduced draw thickness .038)

It is requested that ballistic limits be determined of the flat sheet stock of the thicknesses listed above as well as the ballistic limits of the helmets at the number 4 and 8 stations as described in paragraph 1. This test will supersede that requested in a letter from this office dated 14 Aug. 1944 file O.O. 421/3260.

3. The purpose of these ballistic determinations is to determine whether or not the slight changes in curvature and design of the helmet will increase the ballistic characteristics. It is requested that these ballistic determinations be expedited and a report be made by indorsement of the results.

By order of the Chief of Ordnance:
